

A: So you can use AES to encrypt data you encrypt using ECB mode and use AES-256 to encrypt the key you use to encrypt data in ECB mode. When you want to decrypt the data you decrypt the AES-256 key and then decrypt the data using ECB mode. For example:
String publicKey = KeyTo

```
olkit.getKeyPair().getPublic().toString(); byte[]
encryptedKey = AES256.encrypt(publicKey.getBytes(), secretKey); byte[]
encryptedData = AES256.encrypt("abc", encryptedKey); String
secretKey = AES256.decrypt(encryptedKey, "12345678"); String iv =
"12345678"; String data = AES256.decrypt(encryptedData, iv); See how it is
```

not ECB anymore? I actually wrote a small article how to use cryptography in java in case you want to read more about it. Q: Is there a reason why Linux needs so many security levels? It's one thing to secure a system, and another to secure a system that can't be broken in a reasonable amount of time. From my

understanding, Linux is inherently secure, as it's being built on the same OS core as Windows, and uses the same kernel as Windows. However, because there are so many levels of protection, a reasonably-dedicated hacker would be able to break in pretty much any system - right? I have a few questions about this: What exactly

is the difference between the different security levels? What can they even do (in addition to giving away your password)? Are there legitimate reasons to have so many security levels in one OS core? A: As other people have said, Linux is inherently secure because of the underlying POSIX and BSD code. Sure, you can

make your own code much more secure than the rest, but it isn't always worth it. There are also legitimate reasons to have multiple levels of security: Preventing users from accidentally deleting system files. Making sure that everything is secure even when the user has sudo/root access. Making sure that things aren't

being quietly unlocked
when you leave the
computer, and that the
screen lock even
